CME213/ME339 Lecture 7

Erich Elsen

Department of Mechanical Engineering Institute for Computational and Mathematical Engineering Stanford University

Spring 2013

Lesson 7

Lesson Outline

- 2D/3D Blocks and Grids
- GPU vs CPU Philosophy
- GPU Architecture
- Warps and Memory Coalescing
- Matrix Transpose Example
- Shared Memory
- Matrix Transpose with Shared Memory

Elsen CME213/ME339 2 / 46

2D Arrays in Linear Memory

NOT This:

```
float **A = new float*[N];
for (int i = 0; i < N; ++i)
   A[i] = new float[N];

A[row][col] = 5.f;</pre>
```

This:

```
float *A = new float[N * N];
A[row * N + col] = 5.f;
```

- First version requires O(N) calls to new and delete vs 1 call
- First version requires two pointer dereferences for each item
- Chaining pointer dereferences like this is slow, you pay the memory access latency twice
- You can use the [] [] with statically declared arrays where the bounds are given at compile time
- The compiler will automatically convert the first from into the second for you

Elsen CME213/ME339 3 / 46

Grid

Blocks are organized into a 1D, 2D or 3D grid of thread blocks.

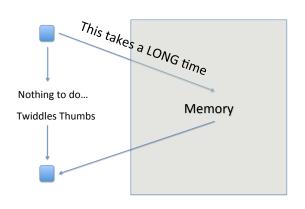

threadIdx: 1D, 2D or 3D index to identify a thread. blockIdx: 1D, 2D or 3D index to identify a block.

blockDim: dimension of the thread block gridDim: dimension of the grid

Elsen CME213/ME339 4 /

CPU Philosophy

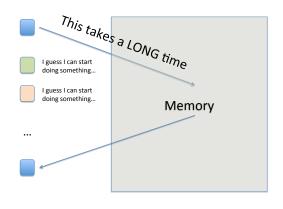

- CPUs aim to reduce latency
- Introduce many levels of large caches to decrease time to get memory
- Majority of transistors are actually cache, they don't actually do any "work"

Elsen CME213/ME339 5 / 46

GPU Philosophy

- GPUs aim to maximize throughput
- Devote more transistors to units that do "work"
- Hide memory latency with parallelism
- While some threads are waiting, swap others in
- Also requires a VERY large register set compared to CPUs

Elsen CME213/ME339 6 / 46

GPU Architecture Overview

7 / 46

SM Overview

- 32 Processing cores
- Shared Memory
- Register File
- Each block runs entirely on one SM

Elsen CME213/ME339 8 / 46

Warps and Memory Coalescing

- Warps are the smallest cooperative unit
- Since beginning of CUDA 32 thread per warp
- Corresponds to the 32 processing cores in an SM
 - Could change someday
- Communication within warps very fast
- Warps cooperate to load memory
- For best performance:
 - Want the locations accessed by threads within a warp to be contiguous
 - Start at a 128-byte boundary
 - Each thread should read at least 4 bytes; 8 is better
 - But not more than 16 bytes

Elsen CME213/ME339 9 /

Warps and Divergence

- All threads in a warp are executed simultaneously
 - Not exactly true on all hardware, but this should be your mental model
- Which means all threads must execute the same instruction
- If different threads want to execute different instructions, this is known as divergence
- Divergence is handled by the hardware for you it will execute the warp as many times as needed to cover all branches
- This can lead to significant slow down due to many idle threads
- Loops that execute for a different number of iterations are also divergent

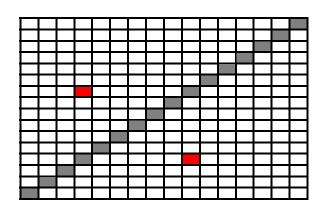

```
if (tid % 2)
  out[tid] = sqrtf(in[tid]);
else
  out[tid] = logf(in[tid]);
6
```

```
while (tid > 1) {
   if (tid % 2)
     tid /= 2;
   else
     tid = 3 * tid + 1;
}
```

Elsen CME213/ME339 10 / 46

Matrix Transposition

M rows; N columns \rightarrow N rows; M columns

$$A(i,j) \rightarrow A(j,i)$$

Elsen CME213/ME339 11 / 46

Simple Implementation

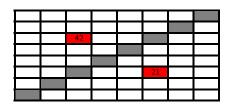

```
1
    __global__
    void simpleTranspose(int *array_in, int *array_out,
2
                          int M, int N)
3
4
      const int tid = threadIdx.x + blockDim.x * blockIdx.x;
5
6
      int col = tid % N; //row, col in INPUT
      int row = tid / N:
9
      array_out[col * M + row] = array_in[row * N + col];
10
    }
11
```

- We assume M * N is a multiple of blockDim.x
- Each block is 1D and the grid is also 1D
- Loc (n, m) in an array of size (M, N) is given by m * N + n

Elsen CME213/ME339 12 / 46

Indexing Example

- The output array is (N, M) and the transposed location is (m, n)
- Accounting for the formula n * M + m
- M = N = 8
- m: 21 / 8 = 2
- n: 21 % 8 = 5
- New Location: 5 * 8 + 2 = 42

Elsen CME213/ME339 13 / 46

Performance

# Array Dimensions	GB/sec
(256, 256)	32
(512, 512)	38
(1024, 1024)	28
(2048, 2048)	22
(4096, 4096)	-

- Invalid configuration argument at the last size due to requesting 65536 blocks
- The max is 65535 move to a 2D grid
- Theoretical peak is 152 GB/sec why such poor performance?
- And why does performance drop with increasing grid size?

Elsen CME213/ME339 14 / 46

Move to 2D

```
__global__
1
   void simpleTranspose2D(int *array_in, int *array_out,
2
                           int M, int N)
3
   {
4
     const int n = threadIdx.x + blockDim.x * blockIdx.x;
5
     const int m = threadIdx.y + blockDim.y * blockIdx.y;
7
     array_out[n * M + m] = array_in[m * N + n];
8
   }
9
```

- Here we are assuming that M is a multiple of blockDim.y and N is a multiple of blockDim.x
- Superficially similar, we trade a modulo and division for a multiply and add

Elsen CME213/ME339 15 / 46

Performance

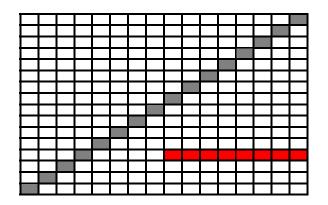

# Array Dimensions	GB/sec
(256, 256)	53
(512, 512)	63
(1024, 1024)	70
(2048, 2048)	69
(4096, 4096)	71

- Performance curve behaves as expected
- Increases with problem size until a plateau is reached
- Performance level has more than doubled
- Why such a difference?

Elsen CME213/ME339 16 / 46

Warp Size of 8

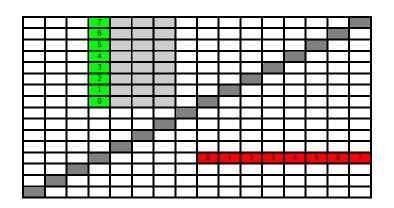

Reads are coalesced

Elsen CME213/ME339 17 / 46

Warp Size of 8

Writes are NOT!

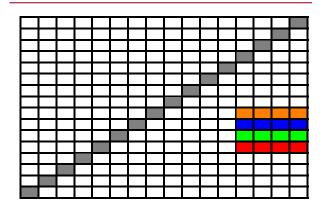

Elsen CME213/ME339 18 / 46

- The reads are fully coalesced
- However, the writes are completely uncoalesced
- For each item that is written a complete 128 byte transaction is made and 124 bytes are wasted
- Explains the low performance, but not why performance drops with increasing size

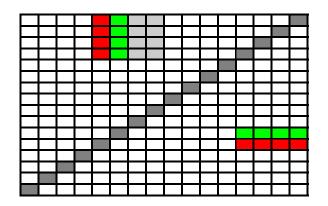

Elsen CME213/ME339 19 / 46

- Memory access pattern is 2D
- Reads might actually be less coalesced depending on dimensions of block
- ullet Previous measurements were taken for 16 imes 16, so each read was only half used but the performance still went up

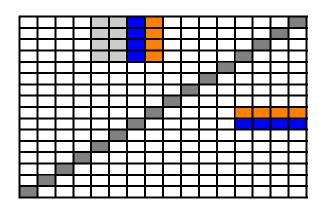

Elsen CME213/ME339 20 / 46

Notice that we have now written two values in each transaction

Elsen CME213/ME339 21 / 46

- Caching!
- The writes of the second warp occur to memory that has been cached because of the first warp's transaction

Elsen CME213/ME339 22 / 46

Cache Hierarchy

- One 768KB L2 cache that serves ALL the SMs
- In the first case then L2 cache is able to hold relevant data for later warps before being evicted
- As the size increases most data gets evicted before it is used again
- In the 2D case we enforce a memory access pattern that ensures we can use data in the L2 before it is evicted

Elsen CME213/ME339 23 / 46

Shared Memory

- Each block can declare memory that is shared amongst its threads
- Each thread can read and write to any location in this memory
- Allows for communication within a block
- Introduces need for synchronization __syncthreads()
- Common pattern:
 - Everyone Read/Write
 - __syncthreads()
 - Everyone Write/Read
- Declare like __shared__ int smemArray[256];
- Smem is a limited resource, maximum of 48Kb available to each block
- Much faster than global memory

Elsen CME213/ME339 24 / 46

Using Smem for Transpose

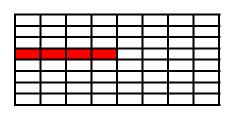

- Main idea is to use smem to allow us to make both reads and writes contiguous
- We can read columns from smem and write rows to global memory

Elsen CME213/ME339 25 / 46

Smem Transpose Memory Read Access Pattern

Global Memory

Shared Memory Transpose

Code Example 1/3

```
__global__
    void fastTranspose(int *in, int *out,
2
                       int M. int N)
3
    {
        const int numWarps = blockDim.y; //let's assume 4
5
        const int warpId = threadIdx.y;
       const int lane = threadIdx.x;
       const int smemRows = 32;
        __shared__ int smem[smemRows][warpSize];
10
11
        int blockCol = blockIdx.x;
12
        int blockRow = blockIdx.y;
13
```

Elsen CME213/ME339 34 / 46

Shared Memory Transpose

Code Example 2/3

```
//load 32x32 block into shared memory
    for (int i = 0; i < smemRows / numWarps; ++i) {</pre>
        int gr = blockRow * smemRows + i * numWarps + warpId;
3
4
        int gc = blockCol * warpSize + lane;
        int row = i * numWarps + warpId;
5
6
        smem[row][lane] = in[gr * N + gc];
7
    }
8
9
    __syncthreads(); //<-- Important!
10
```

Elsen CME213/ME339 35 / 46

Shared Memory Transpose

Code Example 3/3

```
//now we switch to each warp outputting a row, which will read
1
   //from a column in the shared memory
2
   //this way everything remains coalesced
3
    for (int i = 0; i < smemRows / numWarps; ++i) {</pre>
        int gr = blockRow * warpSize + lane;
5
        int gc = blockCol * smemRows + i * numWarps + warpId;
6
        int row = i * numWarps + warpId;
7
8
        out[gc * M + gr] = block[lane][row];
9
   }
10
```

Elsen CME213/ME339 36 / 46

Performance

2D Version w/o Shared Memory

Shared Memory Version

# Array Dimensions	GB/sec
(256, 256)	53
(512, 512)	63
(1024, 1024)	70
(2048, 2048)	69
(4096, 4096)	71

# Array Dimensions	GB/sec
(256, 256)	22
(512, 512)	46
(1024, 1024)	57
(2048, 2048)	64
(4096, 4096)	68

It got worse?

Elsen CME213/ME339 37 / 46

Shared Memory

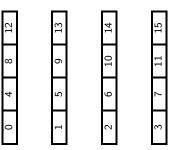

Banks

- We need to understand the concept of banked memory to be able to explain why the performance actually went down
- The actual hardware implementation of shared memory unfortunately doesn't allow for constant time access to arbitrary locations
- Instead there are 32 banks
- Within each bank there is constant time access to arbitrary locations

Elsen CME213/ME339 38 / 46

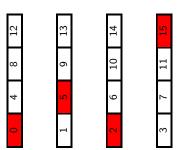

- Suppose we have 4 memory banks
- Columns correspond to banks
- Our warp (of 4 threads) wants to access locations: 0, 2, 5, 15

Elsen CME213/ME339 39 / 46

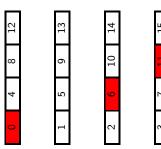

- This is OK
- Each bank needs one value
- No conflicts

Elsen CME213/ME339 40 / 46

- 0, 0, 6, 11
- Each bank needs one value
- No conflicts
- Duplication not a problem

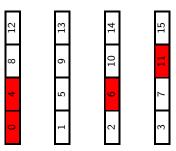

Elsen CME213/ME339 41 / 46

- 0, 4, 6, 11
- Bank 0 needs two values
- Conflict!
- Causes serialization

 it takes twice as long to read these values

Elsen CME213/ME339 42 / 46

Back To The Code

```
//Write out to global memory
for (int i = 0; i < smemRows / numWarps; ++i) {
   int gr = blockRow * warpSize + lane;
   int gc = blockCol * warpSize + i * numWarps + warpId;
   int row = i * numWarps + warpId;

out[gc * M + gr] = block[lane][row];
}</pre>
```

- We can see that each warp reads from the same column of shared memory
- Each row is a multiple of the warp size
- Which means the warp is reading from the same bank

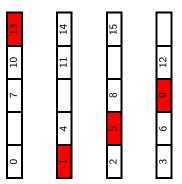

Elsen CME213/ME339 43 / 46

Solution

Make the number of columns coprime to the warp size — easiest is to just add one

```
__shared__ int smem[smemRows][warpSize + 1];
```

Elsen CME213/ME339 44 / 40

New Performance Numbers

2D Version w/o Shared Memory

Shared	Memory Version — No
	Bank Conflicts

# Array Dimensions	GB/sec
(256, 256)	53
(512, 512)	63
(1024, 1024)	70
(2048, 2048)	69
(4096, 4096)	71

# Array Dimensions	GB/sec
(256, 256)	70
(512, 512)	88
(1024, 1024)	112
(2048, 2048)	123
(4096, 4096)	124

Not bad — but we can do even better - next time!

Elsen CME213/ME339 45 / 46

Shared memory and HW3

- You will use smem to increase locality
- By bringing a 2D region into smem, you can compute many grid points without going to global memory
- Reducing global memory traffic should increase performance

Elsen CME213/ME339
